(Received 6 April 2025; revised 14 November 2025; accepted 25 November 2025; published 22 December 2025)

The first observation of coherent $\phi(1020)$ meson photoproduction off heavy nuclei is presented using ultraperipheral lead-lead collisions at a center-of-mass energy per nucleon pair of 5.36 TeV. The data were collected by the CMS experiment and correspond to an integrated luminosity of 1.62 μb^{-1}. The $\phi(1020)$ meson signals are reconstructed via the K^+K^- decay channel. The production cross section is presented as a function of the $\phi(1020)$ meson rapidity in the range $0.3 < |y| < 1.0$, probing gluons that carry a fraction of the nucleon momentum (x) around 10^{-4}. The observed cross section exhibits little dependence on rapidity and is significantly suppressed, by a factor of ~5, compared to a baseline model that treats a nucleus as a collection of free nucleons. Theoretical models that incorporate the nuclear shadowing effect generally provide a better description of the $\phi(1020)$ data than those incorporating gluon saturation. This study establishes a powerful new tool for exploring nuclear effects and nuclear gluonic structure in the small-x regime at a unique energy scale bridging the perturbative and nonperturbative quantum chromodynamics domains.

DOI: 10.1103/2ssw-wwyy

Understanding the fundamental structure of nuclear matter is a central goal of quantum chromodynamics (QCD). At high energies or small x values, where x represents the momentum fraction carried by a parton within a nucleon, gluon densities rise rapidly, leading to gluon dominance in the partonic structure [1]. It is theorized that this growth of gluon density is primarily driven by gluon splitting; however, at small x, nonlinear effects such as gluon recombination are predicted to counterbalance this increase, leading to the phenomenon of "gluon saturation" [2,3]. Heavy nuclei, with significantly higher gluon densities than free nucleons, provide an ideal setting to investigate this phenomenon [4]. Furthermore, nuclear shadowing, which may arise from coherent multinucleon interactions, can also reduce the effective gluon density in nuclei compared to that in free nucleons, thereby also influencing small-x physics [5]. A combined treatment of gluon saturation and nuclear shadowing, though challenging, would be valuable for future theoretical developments.

In ultraperipheral collisions (UPCs) of high-energy heavy ions, a photon emitted by one nucleus can fluctuate into a virtual quark-antiquark pair and interact diffractively with the other nucleus, producing a vector meson (VM) such as a $\rho(770)^0$, $\phi(1020)$, J/ψ, or Υ meson [6–19]. In what follows, the $\phi(1020)$ meson will be referred to as the ϕ meson. This photoproduction process is sensitive to the nuclear gluon distribution [20,21]. If the photon interacts with the entire nucleus, the process is called coherent; if it interacts with its internal constituents, it is called incoherent. At the leading order in perturbative QCD (pQCD), the cross section for coherent VM production scales as $\sigma_{\mathrm{VM}} \propto [xG(x, Q^2)]^2$, where $G(x, Q^2)$ is the gluon density at an energy scale Q^2 that is often taken to be $\sim(Q_0^2 + m_{\mathrm{VM}}^2)$, with $Q_0 \sim 0$ GeV for quasi-real photons [4,22,23]. The VM mass (m_{VM}) is therefore the primary determinant of the energy scale in QCD calculations. The onset of gluon saturation and the applicability of pQCD are highly sensitive to this scale.

While the J/ψ meson probes gluon distributions at relatively large scales ($Q^2 \gtrsim 10$ GeV^2), the ϕ meson, composed of a strange quark-antiquark pair with a mass of 1.019 GeV [24], probes an intermediate regime where both perturbative and nonperturbative QCD dynamics are relevant. Varying the vector-meson mass effectively scans different interaction scales, providing sensitivity to the transition between dilute and dense gluonic matter. Because gluon-saturation models feature an explicit saturation scale $Q_s(x, A)$, whereas nuclear-shadowing models do not, the ϕ meson offers a unique test of their scale dependence. Measuring the coherent photoproduction of ϕ mesons is challenging due to the very low transverse momentum of the decay kaons ($p_{\mathrm{T}}^{\mathrm{trk}} < 0.15$ GeV), which

limits the detector acceptance and particle identification efficiency. This has prevented ϕ mesons from being used as probes in previous UPC studies.

This Letter presents the first measurement of coherent ϕ meson photoproduction in heavy ion UPCs. The ϕ meson is reconstructed via the decay channel $\phi \to K^+K^-$ using PbPb collision data collected by the CMS detector at the CERN LHC at a center-of-mass energy per nucleon pair of $\sqrt{s_{\mathrm{NN}}} = 5.36$ TeV. The dataset corresponds to an integrated luminosity of 1.62 ± 0.10 $\mu\mathrm{b}^{-1}$. The differential cross section is reported as a function of ϕ meson rapidity for the range $0.3 < |y| < 1.0$, probing x values around 10^{-4}. Acceptance and efficiency limitations in reconstructing $K^{\pm}$ mesons restrict the measurable coherent ϕ meson yield to this rapidity range. The results are compared with a wide range of theoretical predictions that include gluon saturation or nuclear shadowing effects. The tabulated results are provided in the HEPData record [25].

The central feature of the CMS apparatus [26] is a superconducting solenoid with an internal diameter of 6 m, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker [27], a lead tungstate crystal electromagnetic calorimeter [28], and a brass and scintillator hadron calorimeter, each composed of a barrel and two end cap sections, providing pseudorapidity (η) coverage $|\eta| < 3.0$. The hadron forward (HF) calorimeter [29] is divided into two halves, one on either side of the interaction region, with each half segmented in $0.175 \times 0.175(\Delta\eta \times \Delta\phi)$ "towers." This detector extends the η coverage provided by the barrel and end cap detectors into the range $3.0 < |\eta| < 5.2$. The CMS apparatus can be used to detect and identify electrons, muons, photons, and hadrons [27–30]. The silicon pixel and strip tracker is capable of reconstructing charged particles with $p_{\mathrm{T}}^{\mathrm{trk}}$ values down to 0.05 GeV. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Refs. [26,31].

Events are selected using a zero-bias trigger with an additional online requirement of at least one reconstructed pixel track, achieving about 90% efficiency for detecting at least one daughter kaon from a ϕ meson in the analysis phase space. In a subsequent off-line selection, events must have a primary interaction vertex, formed by at least two tracks coming from the collision, that is within 25 cm along the beam axis and within 2 cm in the transverse plane from the detector center.

To select UPC events, the largest energy deposit in any of the HF calorimeter towers must fall below a tower specific threshold determined from empty bunch crossing events. This eliminates nearly all hadronic events while maintaining negligible loss of UPC signal efficiency [32]. Furthermore, events are required to have exactly two "high purity tracks" (as defined in Ref. [27]) with opposite electric charges, and with $p_{\mathrm{T}}^{\mathrm{trk}} > 0.05$ GeV and $|\eta| < 2.4$.

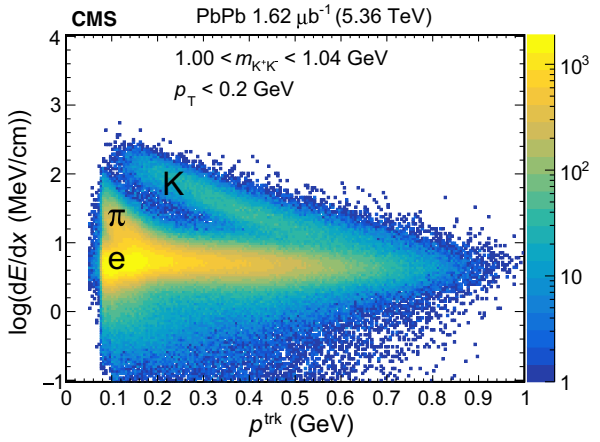

FIG. 1. The $\log(\mathrm{d}E/\mathrm{d}x)$ distribution of daughter tracks of coherent ϕ candidates with $p_{\mathrm{T}} < 0.2$ GeV, selected within the signal invariant mass region, as a function of the daughter track total momentum, p^{trk}.

The kaon identification is performed using the energy loss information ($\mathrm{d}E/\mathrm{d}x$) measured by the pixel detector, as illustrated in Fig. 1, following a probability-based method described in Refs. [33,34]. Here and throughout the rest of the Letter, p_{T} refers to the transverse momentum of the K^+K^- pair.

The probability of producing an energy loss value ε at a total momentum p^{trk} for a given charged particle species k (k can be $\pi^{\pm}$, $K^{\pm}$, proton p, or antiproton $\bar{p}$) can be approximated by

$$P_k(\varepsilon|p^{\mathrm{trk}}) = \frac{1}{\sqrt{2\pi}\sigma_k}\exp\left(-\frac{(\varepsilon-\mu_k)^2}{2\sigma_k^2}\right), \qquad (1)$$

where $\varepsilon = \log(\mathrm{d}E/\mathrm{d}x)$, and μ_k and σ_k are the corresponding values for the momentum dependent mean and width, respectively, of the ε distribution for species k. As the pair production of p and $\bar{p}$ is strongly suppressed because of the lack of coupling to VM photoproductions in UPC events [6], the selected two-track events mainly contain pions and kaons. To select high-quality K^+K^- events, each track is required to satisfy $P_K(\varepsilon|p^{\mathrm{trk}}) > 10P_\pi(\varepsilon|p^{\mathrm{trk}})$.

The K^+K^- pairs with an invariant mass within a range of $0.98 < m_{K^+K^-} < 1.15$ GeV are selected for the signal extraction of ϕ mesons. These K^+K^- pairs mainly include both $\phi \to K^+K^-$ decays and direct K^+K^- pairs from photon-nuclear interactions. Direct pairs are produced when a photon fluctuates into a virtual K^+K^- pair and elastically scatters off the target nucleus, forming a real K^+K^- pair. These pairs contribute as a smooth continuum background in the $m_{K^+K^-}$ distribution. Contamination from misidentified $\pi^+\pi^-$ pairs originating from coherently produced ρ decays and direct $\pi^+\pi^-$ pairs is estimated by assigning the K mass to the charged pions produced in Monte Carlo (MC) samples. The pion pair contamination

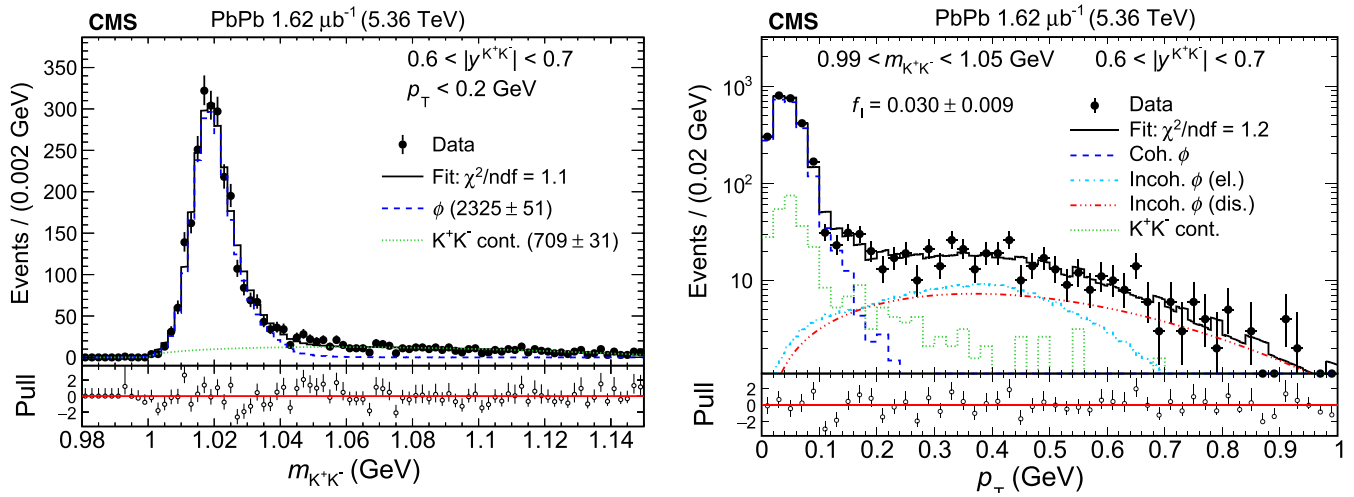

FIG. 2. Examples of the invariant mass ($m_{K^+K^-}$) distribution in the coherent process dominant region of pair $p_T < 0.2$ GeV (left) and the pair p_T distribution in the ϕ meson mass window $0.99 < m_{K^+K^-} < 1.05$ GeV (right). The curves show results of the template fit, including the coherent (Coh.) ϕ, incoherent (Incoh.) ϕ for both elastic (el.) and dissociative (dis.) processes, and the direct K^+K^- continuum (cont.). The error bars represent statistical uncertainties (σ_{Data}). The bottom panels show fit pulls, $(\text{Data} - \text{Fit})/\sigma_{\text{Data}}$, with red lines at zero.

contributes only a negligible ~0.01% to the total observed yield in the signal mass range.

The ϕ meson raw yield (N_ϕ^{raw}) is extracted via a χ^2 template fit to the $m_{K^+K^-}$ distribution in the low K^+K^- transverse momentum region $p_T < 0.2$ GeV, where the coherent process dominates, as illustrated in Fig. 2 (left). The signal template shape of coherent ϕ meson production is obtained from the STARlight (v3.30) event generator [35], together with a full CMS detector simulation, as implemented with Geant4 [36]. Similar to previous studies [37–39], the continuum background of direct K^+K^- pairs is described by an empirical function $f_{\text{bkg}}(m) = A(m - 2m_K)^{1/2} + B(m - 2m_K)^{3/2}$, where A and B are free parameters. This function accounts for the experimental threshold effects near twice the kaon mass. A recent ALICE study [40] reported a hint of enhanced direct K^+K^- yield in the mass range $1.1 < m_{K^+K^-} < 1.4$ GeV with a significance of 2.1σ. This enhancement is attributed to potential interference effects between $\phi \to K^+K^-$ decay and direct K^+K^- production. However, the absence of a direct ϕ meson measurement prevents a definitive conclusion regarding this explanation. A theoretical study [41] suggests that such interference effects are negligible near the ϕ meson peak and become significant only at higher masses ($m_{K^+K^-} > 1.2$ GeV). In this analysis, the χ^2/ndf (where ndf is the number of degrees of freedom) value and the pull distribution, as shown in the lower panel of Fig. 2 (left), indicate that the fit without incorporating interference effects provides an accurate description of the data. This observation is consistent with the expectation of Ref. [41].

The extracted N_ϕ^{raw} value includes contributions from both coherent and incoherent photoproduction. The fraction of the incoherent contribution (f_I) is determined by fits to the pair p_T distributions within the ϕ mass window. Incoherent processes can be either elastic or dissociative, depending on whether the interacting nucleon remains intact or dissociates after the interaction, respectively. The template p_T shapes of coherent and elastic incoherent ϕ meson photoproduction processes are from the STARlight simulations. The p_T distribution of the dissociative incoherent process is described by the function $dN/dp_T \approx p_T e^{b_{\text{pd}} p_T^2}$, as employed by the ZEUS experiment [42], where b_{pd} is a free parameter in the fit. The p_T distribution of the K^+K^- continuum is obtained from the higher-sideband region of the ϕ signal peak ($1.05 < m_{K^+K^-} < 1.15$ GeV), while its normalization factor is fixed to the yield within the ϕ mass window determined in the full p_T range up to 1 GeV. The default configuration of STARlight does not perfectly simulate the p_T spectra of coherent VM photoproductions observed in recent measurements [12,15,16,43–45]. In Ref. [43], it was pointed out that this issue can be overcome by enlarging the nuclear radius parameter. Changing the Pb radius parameter from 6.67 to 8.67 fm allows STARlight to match the measured ϕ p_T spectra and, consequently, the larger radius value is used here. In the fit, the normalization factors are free for the coherent, elastic incoherent and dissociative incoherent ϕ meson photoproduction. The incoherent contamination fraction can be obtained as $f_I = [N_{\text{incoh}}^{\text{el}} + N_{\text{incoh}}^{\text{dis}}]/N_{\text{coh}}$ in the low-p_T (< 0.2 GeV) region. A representative fit to the p_T spectrum of the K^+K^- pairs within the ϕ meson mass window is shown in Fig. 2 (right). The extracted f_I values in different rapidity intervals are found to be in the range 3%–5%.

The differential cross section of coherent ϕ meson photoproduction is determined using the expression

$$\frac{d\sigma_{\phi}^{\mathrm{coh}}}{dy} = \frac{N_{\phi}^{\mathrm{raw}}}{(1+f_{\mathrm{I}})(\mathcal{A}\epsilon)_{\phi}\mathcal{B}_{\phi\to K^{+}K^{-}}\mathcal{L}_{\mathrm{int}}\Delta y}, \tag{2}$$

where N_{ϕ}^{raw} is the ϕ meson yield extracted within $p_{\mathrm{T}} < 0.2$ GeV, f_{I} is the incoherent fraction, $(\mathcal{A}\epsilon)_{\phi}$ is the product of detector acceptance and efficiency for reconstructing the coherent ϕ meson photoproduction, $\mathcal{B}_{\phi\to K^{+}K^{-}} = (49.1 \pm 0.5)\%$ is the world-average branching fraction [24], Δy is the width of the rapidity interval, and $\mathcal{L}_{\mathrm{int}}$ is the integrated luminosity of the data sample. The $(\mathcal{A}\epsilon)_{\phi}$ factor is determined from simulation, with values between 12% and 36% for the ϕ meson rapidity range of $0.3 < |y| < 1.0$. The dominant efficiency loss arises from the requirement on the minimum number of hits per track. This condition is less often satisfied for tracks at mid-rapidity, where large curvature in the strong magnetic field reduces the number of tracker hits. Additional corrections using the "tag-and-probe" (TnP) method [46,47] are applied to account for data-to-simulation discrepancies in the description of the online trigger and kaon reconstruction efficiencies. In this approach, one kaon track from $\phi \to K^{+}K^{-}$ decays is tightly selected ("tag"), while the second ("probe") is a loosely reconstructed pixel-seed track used to determine the probability of satisfying the online trigger, as well as the off-line full reconstruction and PID criteria. The resulting scale factors are about 0.85 in the ϕ meson rapidity range. The reported cross section does not include contributions from coincident ultraperipheral collisions; any residual effect ($< 2\%$) is included in the systematic uncertainty.

Systematic uncertainties are evaluated by taking the maximum deviation from the nominal result for each given uncertainty source. The uncertainties are 6.4% in the integrated luminosity and 1% in the $\mathcal{B}_{\phi\to K^{+}K^{-}}$ [24]. Uncertainties propagated from the TnP scaling factors are estimated to be 2%–6%. The threshold energies in the HF calorimeter used to reject hadronic contamination are tightened on both sides, which leads to a 2%–3% uncertainty. The uncertainty from the raw signal yield extraction is evaluated by using the alternative background model employed in Ref. [38] and by varying the range of the $m_{K^{+}K^{-}}$ for the fit. Overall, the uncertainties from signal yield extraction are found to be 3%–6%. The systematic uncertainty in the incoherent fraction is estimated by (i) using the coherent ϕ meson production template with the default nuclear parameters in STARlight, (ii) varying the range of the mass sideband for the $K^{+}K^{-}$ continuum template, and (iii) removing the elastic incoherent ϕ template from the fit for the incoherent fraction estimation. The uncertainty from the incoherent fraction is less than 1%. Individual sources of systematic uncertainties are added in quadrature to obtain the total systematic uncertainty of 7%–10%.

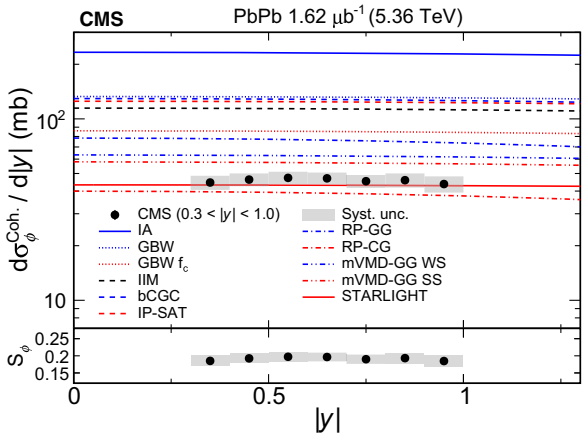

FIG. 3. The differential cross section of coherent ϕ meson photoproduction as a function of rapidity in the range $0.3 < |y| < 1.0$ (top panel). Vertical bars and shaded bands indicate statistical and systematic uncertainties, respectively. Theoretical predictions shown include the impulse approximation (IA) [35], color dipole models (IIM [53], bCGC [54], IP-SAT [55,56], GBW and GBW f_c [57,58]), reggeometric pomeron (RP) models with classical Glauber and Gribov-Glauber approaches [23,59], the modified VMD (mVMD) model with GG and strong or weak shadowing (SS or WS) [50], and STARlight with CG [35]. The bottom panel shows the data-to-IA ratio.

The differential cross section for coherent ϕ meson photoproduction over the rapidity range $0.3 < |y| < 1.0$ is shown in Fig. 3. The characteristic x values of the probed gluons in a given $|y|$ interval can be obtained using

$$x = \frac{m_{\phi}}{\sqrt{s_{\mathrm{NN}}}}\exp(\pm y), \tag{3}$$

where the sign of y corresponds to the rapidity sign of the photon-emitting nucleus in the laboratory frame [20,43,48,49]. However, in symmetric UPCs, the photon emitter cannot be definitively identified [20,50]. Consequently, the cross section values at each $|y|$ represent the average contributions from $+y$ and $-y$, without separating individual contributions. The x values corresponding to the $|y|$ coverage are around 10^{-4}, falling within the range explored in recent measurements [43,51], where the coherent J/ψ meson photoproduction cross section exhibits strong nuclear suppression effects [52].

The data are compared to various theoretical models, all of which are constrained to photoproduction data off protons from HERA [37], either directly or via fitted parameterizations (as in the case of STARlight). A baseline model, referred to as the impulse approximation (IA), represents the direct sum of coherent contributions by treating the nucleus as a simple collection of free nucleons [50,60]. To quantify the impact of nuclear modifications on coherent ϕ meson photoproduction, a nuclear suppression factor, S_{ϕ}, is defined as the ratio of the measured cross

section to the IA prediction [50]. The extracted S_ϕ values, as shown in the bottom panel of Fig. 3, are found to be ~0.18–0.20 across the entire $|y|$ range. This observation provides strong evidence that coherent ϕ meson photoproduction undergoes significant nuclear suppression. Moreover, the value of S_ϕ is approximately half of $S^{J/\psi}$ (0.41 ± 0.05) within the $0 < |y| < 0.8$ range, as reported by the ALICE experiment [16] with PbPb UPCs at $\sqrt{s_{\rm NN}} = 5.02$ TeV. The greater suppression of the ϕ meson confirms the mass dependence in coherent VM photoproductions [5,54,61].

Theoretical calculations that include gluon-saturation effects at small x are performed within the color glass condensate (CGC) framework [3] using the color-dipole formalism [62]. Three representative approaches are compared with the data. The Iancu-Itakura-Munier (IIM) model [53] interpolates between the Balitsky-Fadin-Kuraev-Lipatov [63–65] and Balitsky-Kovchegov [65–67] equations, the bCGC model [54] adds impact-parameter dependence to the saturation scale, and the IP-SAT model [55,56] employs an eikonalized dipole amplitude based on a DGLAP-evolved gluon density [68–70]. All three models overpredict the measured coherent ϕ photoproduction cross section off lead nuclei by a factor of $2.6 - 3.0$.

Notably, a theoretical study [58], based on a framework similar to the bCGC model and known as the Golec-Biernat-Wusthoff (GBW) model, specifically investigates non-pQCD corrections to the photon wave function within the color dipole formalism. The predictions without and with these corrections, referred to as GBW and GBW f_c, respectively, are shown in Fig. 3. The inclusion of non-pQCD corrections results in an additional reduction of approximately 40% in the predicted cross sections, but the predictions still overestimate the data by a factor of about 2.

In contrast to gluon-saturation models, another class of calculations accounts for nonlinear QCD effects at small x through *nuclear shadowing*. These models generally use the vector meson dominance (VMD) picture [71] combined with either the classical Glauber (CG) [72] or the Gribov-Glauber (GG) [73] formalism to describe multiple scatterings of the virtual vector meson in the nucleus. While CG includes only elastic interactions, GG extends the treatment to inelastic channels. The reggeometric Pomeron (RP) model [23,59] combines VMD with both CG and GG schemes, with the latter predicting cross sections roughly twice as large. The CG-based results and the modified VMD (mVMD) approach with strong or weak shadowing scenarios [50] describe the data more closely, though they still overshoot by 25%–35%. Predictions from the STARlight model [35], which employs VMD with the CG formalism, agree with the measurements within a few percent, despite its known limitations for coherent $\rho(770)^0$ and J/ψ production [16,18,43,51,74,75].

In summary, the first measurement of coherent $\phi(1020)$ meson photoproduction off a heavy nucleus has been performed by the CMS experiment in ultraperipheral lead-lead collisions at a center-of-mass energy per nucleon pair of 5.36 TeV. The production cross section is reported in the ϕ meson rapidity range $0.3 < |y| < 1.0$, probing gluons within the lead nucleus having x values around 10^{-4} at an intermediate energy scale set by the ϕ meson mass. This places it in a unique regime between perturbative and nonperturbative quantum chromodynamics. The cross section is found to be significantly suppressed by a factor of ~5 compared to an impulse approximation model that treats a nucleus as a collection of free nucleons. Models that account for nuclear shadowing effects generally provide better predictions of the data compared to those that incorporate gluon saturation effects. The measurement of coherent ϕ meson photoproduction off a heavy nucleus establishes a powerful new tool for exploring nuclear effects and nuclear gluonic structure in the small-x regime.

Acknowledgments—We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid and other centers for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC, the CMS detector, and the supporting computing infrastructure provided by the following funding agencies: SC (Armenia), BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES and BNSF (Bulgaria); CERN; CAS, MoST, and NSFC (China); MINCIENCIAS (Colombia); MSES and CSF (Croatia); RIF (Cyprus); SENESCYT (Ecuador); ERC PRG, RVTT3 and MoER TK202 (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); SRNSF (Georgia); BMBF, DFG, and HGF (Germany); GSRI (Greece); NKFIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LMTLT (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MES and NSC (Poland); FCT (Portugal); MESTD (Serbia); MICIU/AEI and PCTI (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); MHESI and NSTDA (Thailand); TUBITAK and TENMAK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

Data availability—Release and preservation of data used by the CMS Collaboration as the basis for publications is

guided by the CMS data preservation, re-use, and open access policy [76].

[190]An institute or international laboratory covered by a cooperation agreement with CERN
[191]An institute formerly covered by a cooperation agreement with CERN

[a]Deceased.
[b]Also at Yerevan State University, Yerevan, Armenia.
[c]Also at TU Wien, Vienna, Austria.
[d]Also at Ghent University, Ghent, Belgium.
[e]Also at Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil.
[f]Also at FACAMP—Faculdades de Campinas, Sao Paulo, Brazil.
[g]Also at Universidade Estadual de Campinas, Campinas, Brazil.
[h]Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil.
[i]Also at University of Chinese Academy of Sciences, Beijing, China.
[j]Also at China Center of Advanced Science and Technology, Beijing, China.
[k]Also at China Spallation Neutron Source, Guangdong, China.
[l]Present address: Henan Normal University, Xinxiang, China.
[m]Also at University of Shanghai for Science and Technology, Shanghai, China.
[n]Present address: The University of Iowa, Iowa City, Iowa, USA.
[o]Also at Zewail City of Science and Technology, Zewail, Egypt.
[p]Also at British University in Egypt, Cairo, Egypt.
[q]Present address: Ain Shams University, Cairo, Egypt.
[r]Also at Purdue University, West Lafayette, Indiana, USA.
[s]Also at Université de Haute Alsace, Mulhouse, France.
[t]Also at Istinye University, Istanbul, Turkey.
[u]Also at Tbilisi State University, Tbilisi, Georgia.
[v]Also at Another institute or international laboratory covered by a cooperation agreement with CERN.
[w]Also at The University of the State of Amazonas, Manaus, Brazil.
[x]Also at University of Hamburg, Hamburg, Germany.
[y]Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany.
[z]Also at Bergische University Wuppertal (BUW), Wuppertal, Germany.
[aa]Also at Brandenburg University of Technology, Cottbus, Germany.
[bb]Also at Forschungszentrum Jülich, Juelich, Germany.
[cc]Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland.
[dd]Also at HUN-REN ATOMKI—Institute of Nuclear Research, Debrecen, Hungary.
[ee]Present address: Universitatea Babes-Bolyai—Facultatea de Fizica, Cluj-Napoca, Romania.
[ff]Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary.
[gg]Also at HUN-REN Wigner Research Centre for Physics, Budapest, Hungary.
[hh]Also at Physics Department, Faculty of Science, Assiut University, Assiut, Egypt.
[ii]Also at Punjab Agricultural University, Ludhiana, India.
[jj]Also at University of Visva-Bharati, Santiniketan, India.
[kk]Also at Indian Institute of Science (IISc), Bangalore, India.
[ll]Also at Amity University Uttar Pradesh, Noida, India.
[mm]Also at UPES—University of Petroleum and Energy Studies, Dehradun, India.
[nn]Also at IIT Bhubaneswar, Bhubaneswar, India.
[oo]Also at Institute of Physics, Bhubaneswar, India.
[pp]Also at University of Hyderabad, Hyderabad, India.
[qq]Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany.
[rr]Also at Isfahan University of Technology, Isfahan, Iran.
[ss]Also at Sharif University of Technology, Tehran, Iran.
[tt]Also at Department of Physics, University of Science and Technology of Mazandaran, Behshahr, Iran.
[uu]Also at Department of Physics, Faculty of Science, Arak University, ARAK, Iran.
[vv]Also at Helwan University, Cairo, Egypt.
[ww]Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy.
[xx]Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy.
[yy]Also at Università degli Studi Guglielmo Marconi, Roma, Italy.
[zz]Also at Scuola Superiore Meridionale, Università di Napoli "Federico II," Napoli, Italy.
[aaa]Also at Fermi National Accelerator Laboratory, Batavia, Illinois, USA.
[bbb]Also at Lulea University of Technology, Lulea, Sweden.
[ccc]Also at Consiglio Nazionale delle Ricerche—Istituto Officina dei Materiali, Perugia, Italy.
[ddd]Also at Institut de Physique des 2 Infinis de Lyon (IP2I), Villeurbanne, France.

[eee]Also at Department of Applied Physics, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Malaysia.
[fff]Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico.
[ggg]Also at INFN Sezione di Torino, Università di Torino, Torino, Italy, Università del Piemonte Orientale, Novara, Italy.
[hhh]Also at Trincomalee Campus, Eastern University, Sri Lanka, Nilaveli, Sri Lanka.
[iii]Also at Saegis Campus, Nugegoda, Sri Lanka.
[jjj]Also at National and Kapodistrian University of Athens, Athens, Greece.
[kkk]Also at Ecole Polytechnique Fédérale Lausanne, Lausanne, Switzerland.
[lll]Also at Universität Zürich, Zurich, Switzerland.
[mmm]Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria.
[nnn]Also at Laboratoire d'Annecy-le-Vieux de Physique des Particules, IN2P3-CNRS, Annecy-le-Vieux, France.
[ooo]Also at Near East University, Research Center of Experimental Health Science, Mersin, Turkey.
[ppp]Also at Konya Technical University, Konya, Turkey.
[qqq]Also at Izmir Bakircay University, Izmir, Turkey.
[rrr]Also at Adiyaman University, Adiyaman, Turkey.
[sss]Also at Bozok Universitetesi Rektörlügü, Yozgat, Turkey.
[ttt]Also at Marmara University, Istanbul, Turkey.
[uuu]Also at Milli Savunma University, Istanbul, Turkey.
[vvv]Also at Kafkas University, Kars, Turkey.
[www]Present address: Istanbul Okan University, Istanbul, Turkey.
[xxx]Also at Hacettepe University, Ankara, Turkey.
[yyy]Also at Erzincan Binali Yildirim University, Erzincan, Turkey.
[zzz]Also at Istanbul University—Cerrahpasa, Faculty of Engineering, Istanbul, Turkey.
[aaaa]Also at Yildiz Technical University, Istanbul, Turkey.
[bbbb]Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom.
[cccc]Also at IPPP Durham University, Durham, United Kingdom.
[dddd]Also at Monash University, Faculty of Science, Clayton, Australia.
[eeee]Also at Università di Torino, Torino, Italy.
[ffff]Also at Bethel University, St. Paul, Minnesota, USA.
[gggg]Also at Karamanoğlu Mehmetbey University, Karaman, Turkey.
[hhhh]Also at California Institute of Technology, Pasadena, California, USA.
[iiii]Also at United States Naval Academy, Annapolis, Maryland, USA.
[jjjj]Also at Bingol University, Bingol, Turkey.
[kkkk]Also at Georgian Technical University, Tbilisi, Georgia.
[llll]Also at Sinop University, Sinop, Turkey.
[mmmm]Also at Erciyes University, Kayseri, Turkey.
[nnnn]Also at Horia Hulubei National Institute of Physics and Nuclear Engineering (IFIN-HH), Bucharest, Romania.
[oooo]Also at Another institute formerly covered by a cooperation agreement with CERN.
[pppp]Also at Texas A&M University at Qatar, Doha, Qatar.
[qqqq]Also at Yerevan Physics Institute, Yerevan, Armenia.
[rrrr]Also at Imperial College, London, United Kingdom.
[ssss]Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan.
